6. In *chem.*, the repeated vaporization and condensation of a substance in distillation.—**7.** In *math.*, the amount of flow round a closed path or circuit; the line-integral round a closed curve of the component velocity of a fluid along the curve.—**Circulation of the blood**, the passage of the blood from the heart into the arteries, from them into the veins, and through the veins back to the heart. The blood passes from the right auricle to the right ventricle, and from the right ventricle by the pulmonary artery to the capillaries of the lungs, where it gives off carbon dioxid and takes up oxygen. From the capillaries of the lungs it returns to the heart, and flows into the left auricle through the four pulmonary veins; thence it goes to the left ventricle, and thence by the aorta to distribute itself over the body. Passing from the arteries through the capillaries into the veins, it returns to the right auricle through the superior and inferior vena cava. The blood-vessels form a continuous system without visible pores; but there is continual leakage of the blood-plasma into the tissues, as well as passage of oxygen through the walls of the vessels; and while there is some reëntrance of substances from the tissues into the blood, there is also provided in the lymphatic vessels a system of drains which takes up from the tissues the leakage from the blood-vessels, changed as it is by all that it has received from and given up to the tissues. These lymphatics pour their contents into the thoracic duct, which discharges into the veins at the union of the veins from the head and neck on the left side; except that the lymphatics from the right side of the head and the right arm and shoulder empty into the veins at the corresponding point on the right side. The velocity of the circulation is greatest as it leaves the heart, diminishes as it proceeds to the capillaries, and increases as it comes back to the heart again in the great veins. It is estimated as from 15 to 20 inches per second in the aorta, on the average, and in the capillaries as .02 to .03 of an inch per second. The time for the complete circuit in man is a little less than half a minute. The tension of the blood in the human aorta is probably between 5.90 and 7.87 inches of mercury above the atmospheric pressure. It diminishes continuously in the arteries, capillaries, and veins, and in the large venous trunks near the heart, as the subclavian, becomes slightly less than the atmospheric pressure, and is called *negative*. The circulation of the blood was first correctly described and fully established by Harvey (1628); but the exact way in which the blood passed from the arteries to the veins was unknown until Malpighi discovered the capillaries (1661). In the mean time the main features of the lymphatic system had been worked out by Bartholin and others. The determination of blood pressures and velocities and the functions of the vasomotor nerves has been the work almost entirely of the present century.—**Collateral circulation**, in *physiol.*, the passage of the blood from one part to another of the same system of vessels by collateral communicating channels. It is much more frequent in the veins than in the arteries.

It was invented by one Diocles, a geometer of the second century B. C., with a view to the solution of the famous problem of the duplication of the cube, or the insertion of two mean proportionals between two given straight lines. Its equation is $x^3=y^2(a-x)$. In the cissoid of Diocles the generating curve is a circle; a point A is assumed on this circle, and a tangent M M' through the opposite extremity of the diameter drawn from A; then the property of the curve is that if from A any oblique line be drawn to MM', the segment of this line between the circle and its tangent is equal to the segment between A and the cissoid. But the name has sometimes been given in later times to all curves described in a similar manner, where the generating curve is not a circle.

They led a contemplative and very ascetic life, and, having emancipated themselves from the oversight of the bishops, formed a sort of religious republic, under the government of a high council of twenty-five members, the abbot of Cîteaux being president. St. Bernard, abbot of Clairvaux (founded 1115), was the most celebrated member of the order, and is regarded as its second founder. Its discipline was afterward greatly relaxed, and several times reformed. From the Cistercians emanated the barefooted monks or Feuillants in France, the nuns of Port-Royal, and the monks of La Trappe. The French revolution reduced the Cistercians to a few convents in Belgium, Austria, Poland, and the Saxon part of Upper Lusatia. They wear a white cassock with a black scapular, but when officiating are clothed with a large white gown, with great sleeves and a hood of the same color. The Cistercians have abbeys in the United States at Gethsemane in Kentucky, and near Dubuque in Iowa.

4. A member of the state or nation; one bound to the state by the reciprocal obligation of allegiance on the one hand and protection on the other. Persons of the following classes are citizens of the United States: (1) Persons born in the United States and not subject to any foreign power (except untaxed Indians). This includes children of alien parents other than those of foreign ambassadors, etc. (2) Children born elsewhere to fathers who were, at the time of their birth, citizens at some time resident in the United States. (3) Naturalized persons, including some in effect naturalized by treaty, etc. (4) Women (though not born here nor naturalized) if not incapable of naturalization, and married to citizens. (5) Freedmen under the act of emancipation. (6) Indians born within the United States who have withdrawn from the tribal relation, entered civilized life, and are taxed. (7) Indians who have accepted lands allotted in severalty under the Dawes Bill (1887); but there may be a question whether they practically become citizens before their reservation is thrown open. A person may be a citizen of the United States without being a citizen of any particular State, as, for instance, an inhabitant of the District of Columbia. The two citizenships are distinct in legal contemplation, although one is usually held by any person who holds the other; and practically, as a general rule, citizenship in a State consists of citizenship of the United States plus a domicile (that is, a fixed abode) in the State. The right to vote or hold office is not a test of citizenship, for minors and women are commonly citizens without those rights, and there are cases where aliens may hold office.

All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are *citizens* of the United States, and of the state wherein they reside.
Const. of U. S., 14th Amendment.

5. A private person, as opposed to a civil official or a soldier: as, a police officer in *citizen's* dress.—**Natural-born citizen**, one who is a member of a state or nation by virtue of birth. Whether it is necessary to this that the father should be a citizen is disputed; those jurists who follow the doctrine of national character prevailing in continental Europe hold that it is; American jurists generally hold that it is not. The English courts, while holding that a child born within the allegiance and jurisdiction is a natural-born British subject irrespective of alien parentage, held also, after much conflict of opinion, and in disregard of abstract consistency, that a child born in a foreign country of British parents was also a natural-born British subject. The American rule is that a child born and remaining within the exclusive jurisdiction of the United States is a citizen, and within its allegiance and protection, irrespective of the birth or nationality of its parents.—**Naturalized citizen**, one of foreign birth who has become a citizen by adoption or naturalization, as distinguished from a native-born or natural-born citizen.

The clan is a tribal form of social and political organization based upon kinship of the members. The chief features of the system are (1) the leadership of a chief, regarded as representing a common ancestor, and (2) the possession of land partly undivided as the common domain of the clan, and partly divided as the separate property of its members and their heirs, the clan being the heir of a member who dies leaving no son. It prevailed in early times in Germany and Ireland, and until recently in Scotland, and to some extent in other countries. Thus, among the Highlanders a clan consisted of the common descendants of the same progenitor, under the patriarchal control of a chief, who represented the common ancestor, and who was revered and served by the clansmen with the blind devotion of children. The clans did not, however, acknowledge the principle of primogeniture, often raising to the chiefship a brother or an uncle of a deceased chief. The name of the clan was generally that of the original progenitor with the prefix *Mac* (son). There are few traces of this institution now remaining.

Each trained to arms since life began,

Specifically—(*a*) A number of pupils in a school, or of students in a college, of the same grade or pursuing the same studies; especially, in American colleges, the students collectively who are graduated, or in accordance with the rules of the college will be graduated, in the same year. There are four college classes, the freshman or lowest, the sophomore, the junior, and the senior. The word was first used in this sense in American colleges in the Latin form *classis*, and was borrowed from the universities of continental Europe, where it had during the sixteenth century replaced the medieval *lectio*. (*b*) In the *Meth. Ch.*, one of several small companies, usually numbering about twelve members, into which each society is divided, for more effective pastoral oversight, social meeting for religious purposes, and the raising of money for church work. It ordinarily holds a weekly session called a *class-meeting*, under the charge of one of the members called a *class-leader*, whose duty it is to see every member of his class at least once a week; to give religious instruction, reproof, or comfort, as needed; to receive for the stewards of the church the contributions of the class for the support of the church; to report to the pastor any members needing especial attention, as the sick, backsliders, etc.; and to report on the condition of his class to each Quarterly Conference. 4. A number of objects distinguished by common characters from all others, and regarded as a collective unit or group; a collection capable of a general definition; a kind. See *classification*.

> There is not a more singular character in the world than that of a thinking man. 5. In *nat. hist.*, a group of plants or animals next in rank above the order or superorder, and commonly formed by the union of several orders or superorders: but it may be represented by a single species. See *classification*. In zoölogy the class was the highest division of the animal kingdom in the Linnean system, when the word first acquired its technical zoölogical meaning. Linnæus arranged animals in six classes: *Mammalia*, *Aves*, *Amphibia*, *Pisces*, *Insecta*, *Vermes*; the next groups below

were the orders. In the Cuvierian system a class was the first division of one of the four "great divisions" of the animal kingdom, *Vertebrata*, *Mollusca*, *Articulata*, and *Radiata*; thus Cuvier's four classes of *Vertebrata* were *Mammalia*, *Aves*, *Reptilia*, and *Pisces*. There are now recognized seven or eight subkingdoms or phyla of animals, divided into about thirty-five classes (see *animal kingdom*, under *animal*); the class being the division usually recognized next below the phylum or subkingdom, though some naturalists introduce a *superclass*, or division between the phylum and the class, as *Ichthyopsida* for the classes *Pisces* and *Amphibia*, or *Sauropsida* for the classes *Aves* and *Reptilia*. The class is always superior to the superorder, order, or suborder, and inferior to the kingdom, subkingdom, or phylum. In botany, likewise, the class is the next principal grade of divisions above the order, and in the Linnean system was the highest grade. The subclass, division, and series or group are, however, often variously intercalated as subordinate groupings between the class and the order. The subkingdom *Spermatophyta*, or seed-bearing plants, includes the two classes *Gymnospermæ* and *Angiospermæ*. The subkingdoms *Pteridophyta*, *Bryophyta*, and *Thallophyta* are variously subdivided by different writers. See these terms in the supplement.

The ordinal number of the class of an algebraical surface is the number of tangent planes to the surface through each line of space. A *classic* is properly a book which maintains itself by virtue of that happy coalescence of matter and style, that innate and requisite sympathy between the thought that gives life and the form that consents to every mood of grace and dignity, . . . and which is something neither ancient nor modern, always new and incapable of growing old. *Lowell*, Among my Books, 2d ser., p. 126.

The present practice of making the *classics* of a language the vehicle of elementary grammatical instruction cannot be too strongly condemned. When the *classics* of a language are ground into children who are incapable of appreciating them, the result is often to create a permanent disgust for literature generally.

In natural history classification has been made on two principles, distinguished as the *natural* and the *artificial*: the former aiming to arrange all known plants or animals according to their resemblances, and degrees of resemblance, in the whole plan of their structure; the latter arranging them by some one or more points of resemblance or difference, as may be most convenient and easy, and without regard to other considerations. The widest divisions in zoölogy are called subkingdoms; subkingdoms are divided into phyla or classes, classes into orders, orders into families, families into genera, genera into species, and species into subspecies. There are also intermediate divisions, as subclass, superorder, suborder, subfamily, etc. In botany the present tendency is to conform as nearly as possible to zoölogical classification, although formerly a very different system was employed. See *animal kingdom*, and *class*, 5.—**Cross-classification**, one in which the different classes are subdivided upon a common differentiating principle, so that they are not subordinated to one another. Thus, the division of the population into native and foreign, male and female, is a cross-classification. D. *klassificeren* = G. *classificiren* = Dan. *klassificere*), < NL. *classificare*, classify (cf. *classific*), < L. *classis*, a class, + *facere*, make: see *class*, *n.*, and *-fy*.] To arrange in a class or classes; arrange or group in sets, sorts, or ranks according to some method founded on common characteristics in the objects so arranged.

Speaking strictly, we form a class when we bring together a collection of individuals held in union by the bond of one or more points of community, and when we take care that nothing that is destitute of the point or points of community is admitted into the class: we *classify* when we arrange classes thus constructed on the principle of higher and lower, wider and narrower.

2. A distinct stipulation, condition, proviso, etc.: as, a special *clause* in a contract.—**3.** In *gram.*, one of the lesser sentences which united and modified form a compound or complex sentence. Principal and coördinate clauses separated from the remainder of the sentence can by omission of connectives (conjunctions or relatives), and addition, if necessary, of words from other clauses, resume the form of simple sentences. Dependent clauses often require further changes of mood, tense, and person to become independent sentences.—**Assumption clause**, a clause frequently inserted in a deed of property subject to a mortgage or other debt, whereby the grantee assumes the payment of the debt in exoneration of the original debtor.—**Attestation clause.** See *attestation*.—**Bright's clauses**, provisions in the Irish Land Act, an English statute of 1870, intended to facilitate the formation of a peasant proprietary by enabling tenants to purchase their holdings.—**Clause of accruer.** See *accruer*.—**Clause of devolution**, in *Scots law*, a clause devolving some office, obligation, or duty on a party in a certain event, as, for example, on the failure of another to perform.—**Clause of return**, in *Scots law*, a clause by which the granter of a right makes a particular distinction of it, and provides that in a certain event it shall return to himself.—**Clauses consolidation acts**, a class of English statutes consolidating or combining and condensing into one system of general application provisions which had previously been frequently enacted in the same or varying forms, for each of many different instances, persons, corporations, or places. Like the pianoforte, it had a keyboard and a set of strings on a horizontal frame; but the tone was produced by the pressure of a brass "tangent" raised and held against the string, instead of by the stroke of a hammer. This method of tone-production permitted considerable variation in force and in quality. In many quadrupeds the clavicles are absent or rudimentary, while in birds they are united in a single forked piece, popularly called the *merrythought* or *wishbone*. In many vertebrates below birds clavicles are recognized, but their homology is not always clear. The human clavicle is by some considered to be composed of its body, or clavicle proper, with a mesoscapular segment or acromial epiphysis, a precoracoid or sternal epiphysis, and an omosternum, or interarticular fibrocartilage; but this view is not generally adopted. The material resulting from the decomposition and consequent hydration of the feldspathic rocks, especially granite and gneiss, and of the crystalline rocks in general. As thus formed, it almost always contains more or less sand, or silicious material, mechanically intermixed. After this has been separated, the clay itself is found to consist of a hydrated silicate of alumina, but it is not yet positively made out that there is one definite combination of this kind constituting the essential basis of all the substances to which the name *clay* is applied. All clays contain hygroscopic water, which may be expelled by heating to 212° F.; but they also contain water in chemical combination, and when this is driven off by ignition the clay loses its plasticity, which cannot be restored. Ordinary clay contains more or less lime and other impurities, which render it to a certain extent fusible. The purer varieties are refractory, and are known as *fire-clay* (which see). (See also *pipe-clay*, *china-clay*, *porcelain-clay*, and *kaolinite*.) The plasticity of clay is of great importance, as without this quality it could not be easily worked into the various shapes for which it is used. On what condition it depends has not as yet been clearly made out.

Bradford clay, in *geol.*, a bluish, slightly calcareous clay of the Oölite, well developed near Bradford in England, and remarkable for the number of apiocrinites in it.—**Clay process**, the method of making a stereotype printing-plate from a mold of prepared clay. a subdivision of the Jurassic series, named from the county in England where it is conspicuous. It is the upper one of two sections into which the Oxfordian is divided, the lower one being the Kelloways rock (Callovian). The Oxford clay crops out in England from Dorsetshire through to Yorkshire. It consists mainly of layers of stiff blue clay, and sometimes attains a thickness of 600 feet.—**Potters' clay**, a clay suitable for making the coarser varieties of pottery, or for being worked by the potter.

It consists essentially of carbonate of iron more or less mixed with clay and sand, and often has the form of nodular concretionary masses. It contains from 20 to 50 per cent. of metallic iron, according to its purity.—**Clay marl**, a whitish, smooth, chalky clay.—**Clay pigeon**, a saucer of baked clay used as an artificial flying target in trap-shooting.—**Clay rock**, a rock made up of fine argillaceous detrital material, and chiefly that derived from the decomposition of the feldspars; indurated clay; clayey material sufficiently hardened to be incapable of being used as clay without grinding, but not chemically altered or metamorphosed.—**Clay shale**, clay having a thinly laminated structure. It differs from clay slate, or argillaceous schist, in that the latter has undergone more or less metamorphism, and from this cause has become crystalline and schistose in structure.—**Clay slate**, an argillaceous rock characterized by having a slaty or fissile structure. It consists of detrital or fragmental material which has become consolidated into a rock, and has undergone more or less rearrangement of its constituent particles. (See *metamorphism*, and *metamorphic rocks*, under *metamorphic*.) Roofing-slate is the most characteristic form of clay slate. The tendency of this rock to split into thin plates, making it available for roofing, is ordinarily the result of conditions arising after its deposition and consolidation (see *cleavage*, 3); sometimes, however, this structure is that of the original deposit. Clay slate, or argillaceous schist, often passes gradually into mica schist, and appears to be an incipient stage in the formation of that rock.

They are too large to have been commonly worn as ornaments, and their use is uncertain. It is also almost always divided into thin layers by two sets of joint-planes nearly at right angles to each other and to the bedding. Of these two sets one is usually more distinct, and this is called the *cleat.* The surfaces exposed in mining on the line of this cleat, which are in reality joint-planes of the coal, are called *faces* and *backs.* Called in England *board.*

★**cleavage** (klē'vāj), *n.* [< *cleave*[2] + *-age.*] 1. The act of cleaving or splitting, or the state of being cloven.

2. In *mineral.*, the property possessed by many crystallized minerals of breaking readily in one or more directions, by which means surfaces more or less smooth are obtained. The cleavage shows the direction in which the force of cohesion is least. (Compare *parting.*) It is defined as *perfect* or *eminent, imperfect, interrupted*, etc., according to the ease with which the fracture takes place, and the smoothness of the resulting surface; also *cubic, octahedral, rhombohedral, prismatic, basal*, etc., according to the direction of the fracture.

3. In *geol.*, the property possessed by certain rocks of being easily split or divided into thin layers. It is chiefly the argillaceous rocks in which cleavage is highly developed, and it seems to be the result of metamorphism combined with pressure. The cleavage of roofing-slate is the best illustration of this structure. (See *clay slate*, under *clay.*) Some rocks split into thin layers as a result of stratification, but this is not what is properly understood by cleavage. Tyndall has shown that wax may have planes of cleavage developed in it by pressure; but the only rocks in which cleavage-planes exist in perfection are those which have also undergone some metamorphism. See *metamorphism.*

4. In *embryol.*, segmentation, specifically of the vitellus: distinctively called *egg-cleavage* or *yolk-cleavage.* See *segmentation.*—**Cleavage-cavity,** in *embryol.*, the cavum segmentarium or hollow of a segmented vitellus or yolk which has become a vesicular morula; the interior of a blastula; the cavity of a blastosphere; a blastocœle or blastocœloma.—**Cleavage-globule, cleavage-cell,** a blastomere (which see).—**Cleavage-mass,** in *embryol.*, any cell resulting from the segmentation of the vitellus or yolk of a germinating ovum-cell; a morula-cell.

The first step in the development of the embryo is the division of the vitelline substance into *cleavage-masses.* *Huxley*, Anat. Vert., p. 10.

Foreigners in Rome, and even allied or subject states and cities, were often clients of Roman patricians selected by them as patrons. The number of a patrician's clients, as of a baron's vassals in the middle ages, was a gage of his greatness.

[As used by the Greeks, the word κλίμα denoted properly a slope or an incline, and was applied to mountain-slopes (κλίματα ὀρῶν), but especially to the apparent slope or inclination of the earth toward the pole. Hence the word came gradually to be used as nearly the equivalent of *zone* (but not of the divisions of the earth's surface now so named). A change of "climate" took place, in going north, on arriving at a place where the day was half an hour longer or shorter, according to the season, than at the point from which the start was made. The same was the meaning of the word *climate* as used by the early English navigators (see def. 1). Hence the word *climate* came finally to have the meaning now attached to it.]—**Continental climate.** See *continental*.

★**cloak** (klōk), *n.* [Until recently also spelled *cloke*, < ME. *cloke*, < OF. *cloke*, *cloque*, *cloche*, a cloak (cf. Dan. *klokke*, an under-petticoat), < ML. *cloca*, a cloak (so called from its shape), lit. a bell: see *clock*².] 1. Properly, a loose outer garment without sleeves, worn by either sex as a protection from the weather: now frequently used, though erroneously, for a sleeved outer wrap worn by women. In the sixteenth century the cloak was an article of every-day wear, and was made with large loose armholes, through which the sleeves of the undergarment were passed, as is seen in portraits of Henry VIII. and the nobles of his court. Later it was shortened, and became in common use little more than a cape, though large and long cloaks were still used in traveling. In the latter part of the seventeenth century cloaks were abandoned, except for protection from cold and wet, on account of the changing fashion of the outer coat. Under the name of *Spanish cloak*, this garment was worn from about 1800 to 1840 in Great Britain and America, the shape being a half-circle; it had a broad collar, often of fur or of velvet, which was continued down the edges of the cloak on both sides in breadths of a foot or more. When in use, one of these edges was drawn across the breast and flung over the opposite shoulder with the breadth of fur or velvet turned outward, so as to form a decorative draping, falling from the shoulder behind. The same garment is still worn as the most common winter dress in certain Italian cities.

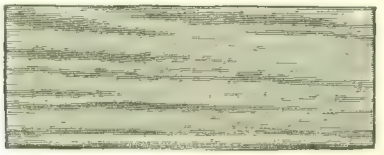
Cf. *cloud*[2].] A collection of particles of water, snow, hail, or dust suspended in the air at any altitude above the earth's surface. The heights of clouds vary ordinarily between a few feet in the case of the lowest stratus up to more than five miles in the case of the highest cirrus; and high above these occasionally float light clouds whose altitudes may extend to twenty miles. The forms, structure, and vapor contents of clouds offer a very great variety. They are usually classified as: (*a*) The *cirrus* (the *cat's-tail* of the sailor), consisting of wavy par-



Cirrus.

allel or divergent filaments, generally at a great height; (*b*) the *cumulus*, dense convex or conical heaps, resting on a horizontal base; (*c*) the *stratus*, an extended, continu-

Cumulus.

ous, level sheet of cloud, increasing from beneath. These three principal forms produce in combination forms denominated as: (*d*) *cirro-cumulus*, a connected system of

Stratus.

small roundish clouds (*mackerel sky*) placed in close order and separated by intervals of sky, often occurring in warm dry weather; (*e*) *cirro-stratus*, a horizontal or slightly inclined sheet, attenuated at its circumference, concave downward or undulated; (*f*) *cumulo-stratus*, a cloud in which the structure of the cumulus is mixed with that of the cirro-stratus or cirro-cumulus, the cumulus at the top and overhanging a flattish stratum or base; (*g*) *nimbus*, *cumulo-cirro-stratus*, or *rain-cloud*, a dense cloud spreading out into a crown of cirrus and passing beneath into a shower; (*h*) *globo-cumulus*, a term applied by Millot to slightly elongated, hemispherical, grayish pockets appearing in the mass of rain-clouds. See the supplement. Aqueous (as distinguished from dust) clouds are formed by cooling moist air to the point of saturation and below. The vapor first condenses upon the dust particles as nuclei; by further cooling the intervening dustless space becomes supersaturated and eventually begins to condense upon the negatively electrified ions; by further cooling the supersaturated vapor may condense upon the positive ions. These electrified ions or electrons have some connection with sunlight; they either emanate from the sun as corpuscles or are formed in our atmosphere by the direct action of the sunshine. The further combination of vapor into water-drops, ice crystals, snowflakes, and hail considered as components of the cloud is explained as far as practicable under those words. As the acceleration of each descending cloud-particle is counterbalanced by the viscosity of the air resisting its motion, it follows that the weight of the clouds is to be considered as a part of the weight of the atmosphere and is added to the barometric pressure of the invisible moist air until the descending cloud-particles and the raindrops have reached the earth's surface. This weight may amount to that of a column of water several feet in height. See the supplement.

2. A solid and more or less distinctly stratified mineral, varying in color from dark-brown to black, brittle, combustible, and used as a fuel, not fusible without decomposition, and very insoluble. It is the result of the transformation of organic matter, and is distinguished by its fossil origin from charcoal (def. 1), which is obtained by the direct carbonization of wood. (See *coal-plant.*) Coal always contains more or less earthy matter, which is left behind in the form of ash after combustion. The quantity of the ash varies considerably, but in good coal does not usually exceed from 5 to 10 per cent. in weight. Coal can, however, be used for fuel, in default of a better material, when the amount of ash is much larger than this. Coal consists essentially of carbon, together with hydrogen, oxygen, and nitrogen; and sulphur is rarely if ever absent. The most general subdivision of coal is into *hard* and *soft.* The former is that coal which consists almost entirely of carbon; the latter is that in which there is a considerable percentage of hydrogen. Hard coal is generally called *anthracite; bituminous coal*, or simply *coal*, is the designation of the ordinary soft coal almost everywhere in general use where coal is burned, except in the eastern and Atlantic United States. In anthracite the bituminous or volatile matter constitutes usually less than 7 per cent. of the whole; in soft or bituminous coal it is usually more than 18 per cent. Coal intermediate in character between anthracite and bituminous coal is called *semi-anthracite* or *semi-bituminous*, according as it approaches anthracite or bituminous coal more nearly in character. The material driven off from coal on ignition is not really bitumen, for coal is insoluble, while bitumen is soluble. The name comes from the fact that bituminous coal behaves on being heated very much as bitumen itself does—that is, it swells up more or less, fuses together, and burns with a bright flame and considerable dense smoke. Coal occurs in all the geological formations, from the lowest in which landplants have been found (the Devonian) up to the highest; but the coal of the great manufacturing countries, England, France, Germany, and the eastern United States, is nearly all of the same geological age, and is obtained from the formation called the Carboniferous. (See *carboniferous.*) The coal of Australia, India, and a part of that of China is of later geological age than the Carboniferous, being Mesozoic, and not Paleozoic. There is also a large quantity of good coal in various parts of the world in formations even more recent than the Mesozoic. In general, however, from the time of the Carboniferous on, the conditions were continually growing less favorable for the formation of coal on a large scale; so that each successive age has less coal to show, and that on an average of poorer quality than the coal of the true Carboniferous epoch. (See *lignite.*) Also called *stone-coal*, *mineral coal*, and formerly *sea-coal.* [*Coal* in this sense is used as a collective noun without a plural; but in Great Britain the plural form is also used in speaking of a quantity of coal, with reference to the pieces composing it: as, to lay in a supply of *coals*; put more *coals* on the fire.]

It is an excellent gas-coal, but too costly to be used for that purpose. It is also called *Torbane Hill mineral* and *torbanite.*—**Bovey coal**, a Tertiary lignite or brown-coal, occurring in beds from 2 to 16 feet thick, in pipe-clay, at Bovey Tracey in Devonshire, England. It is an inflammable fossil, resembling in many of its properties bituminous coal. Its structure is fissile, and its cross-fracture even or conchoidal, with a resinous and somewhat shining luster. It is brittle, burns with a weak flame, and exhales an odor which is generally disagreeable.—**Buckwheat coal.** See *buckwheat.*—**Coal-boring bit.** See *bit*[1].—**Delve of coals.** See *delve.*—**Fibrous coal.** Same as *mother-of-coal* (which see, below).—**Mother-of-coal**, a soft black substance, resembling charcoal in appearance, found in connection with coal, usually along its planes of stratification or lamination, in which the woody character of the material from which the coal was formed is more perfectly preserved than it is in the body of the coal itself. Also called *fibrous coal*, *fossil charcoal*, and *mineral charcoal.*—**Small coal.** (*a*†) Little wood coals formerly used to light fires. *Gay.* (*b*) Same as *slack.*—**To blow a coal**†, to kindle strife.

(See *coal*.) Remains of plants with recognizable characters are not only often distinguishable in the coal itself, but their carbonized fragments, impressions, or casts are usually abundant and clearly discernible in the

shales which form the roof of the coals or intervene between closely situated coaly strata. In these cases the earthy sediments have more or less distinctly isolated the plant fragments, preventing their massing to form beds of coal. The coal-forming vegetation has varied greatly in kind from one geological period to another. In general geological and paleontological usage the terms "coal-plant" and "coal-flora" are restricted to the plant-life of the period of the "great coal formation," that is, the Upper Carboniferous or Coal Measures. The vegetation ("coal-plants" of usage) of this period was overwhelmingly cryptogamic. The chief contributors to the coal were: (1) Ferns, such as *Neuropteris, Pecopteris, Alethopteris, Sphenopteris*, etc.; (2) *Lycopodiales*, principally *Lepidodendron* and *Sigillaria*; (3) *Equisetales*, such as *Calamites, Calamodendron*, and *Annularia* (see these words); and (4) the *Cordaitales* (composite gymnosperms). The plants contributing to the coals of the Mesozoic up to the Upper Cretaceous were chiefly ferns, conifers, and cycads, while the predominant plant-life accompanying coals of the later Cretaceous and the Cenozoic comprised dicotyledonous types, conifers, and ferns.

There are two distinct species of coatis or coatimondis, the synonymy of which has been almost inextricably confused, nearly all the names which have been given to one having been also applied to the other. See *kobold* and *goblin*.] Chemical symbol, Co; atomic weight, 58.97. A metal of a steel-gray color and a specific gravity variously given at from 8.52 to 8.95. It closely resembles nickel, the atomic weights and specific gravities of the two metals being very nearly or quite the same. They have also very nearly the same ductility and tenacity, are almost always found in intimate association, and have in many respects a marked resemblance to iron, but are rather more fusible than that metal, and much less magnetic. Cobalt might be, and is to a very small extent, used for the same purposes for which nickel is used, especially for plating the surface of iron; but it is much rarer than nickel, is procured with more difficulty in the metallic form, and is consequently a dearer metal. The most important ores of cobalt are cobaltite, smaltite, and linnæite. The chief supply of the cobalt preparations comes from Saxony, Bohemia, Hesse, and Norway. The principal value of cobalt in the arts is due to the fact that its silicate furnishes an intense and beautiful blue color, of importance in painting, and especially in the decoration of porcelain and glass. Also spelled *kobalt*.—**Cobalt blue.** See *blue*.—**Cobalt green.** See *green*.—**Cobalt plating,** a method of electroplating by the use of a bath of neutral solution of cobalt and ammonium double sulphate, or cobalt sulphate with ammonium or magnesium sulphate, or cobalt chlorid combined with ammonium and magnesium chlorids. The hackle of the hen is orange, striped with black, her tail black, and the wing-primaries are dark-brown or dull-black. ★**cochineal** (koch'i-nēl or koch-i-nēl'), *n.* [Early mod. E. also *cutchaneal*; = D. *konzenilje* = G. Dan. *cochenille* = Sw. *kochenill* = F. *cochenille* = It. *cocciniglia* = Pg. *coccinella*, < Sp. *cochinilla*, cochineal, < L. *coccineus*, *coccinus*, scarlet, < *coccum*, < Gr. *κόκκος*, a berry, esp. the kermes insect (supposed to be a berry): see *coccus*. The Sp. *cochinilla*, cochineal, is by some referred to *cochinilla*, a wood-louse (to which the cochineal-insect has some resemblance), dim. of *cochina*, a sow, fem. of *cochino*, a pig; cf. E. dial. *sow-bug*, wood-louse.] 1. A dyestuff consisting of the dried bodies of a species of insects, the *Coccus cacti*, found upon several species of *Opuntia* and other *Cactaceæ*, especially *O. Tuna*, *O. Ficus-Indica*, and *Nopalea cochinillifera*. It colors a brilliant crimson, which is changed by acids to an orange-red and by alkalis to violet; a brilliant scarlet dye is prepared from it. The cacti upon which the insect lives, bearing the general name of *nopal*, are extensively cultivated as food for them in the tropical countries of America, and in Java, Algeria, etc. The females only are valuable for their color, and are collected twice a year, after they have been fecundated and have laid eggs sufficient for a new brood. They are killed by spreading them upon heated plates, by putting them in ovens, or by immersing them in boiling water or exposing them to its vapor. Those killed by heated plates are of a blackish color, and are considered to be the finest; they are called *zacatilla*. Those from ovens are next in value; they are of an ash-gray (*blanco* or silver-white) color, and are called *silver cochineal*, or *jaspeada*. Those killed by water or vapor are of a reddish-brown color, and are the least valuable. The fragments, dust, and impurities from cochineal are collected and used as an adulterant, under the name of *granilla*. The finest grade often goes by the name of *mestica* or *mesteque*, and is exported in large quantities from Honduras. Besides the finer grades, which are cultivated insects, a considerable trade is carried on in inferior or wild insects; they are scarcely more than half the size of the cultivated species, and are covered with a cottony down which adds a useless bulk. Good cochineal has the appearance of small, deep brown-red, somewhat purplish grains, wrinkled across the back with parallel furrows, intersected in the middle by a longitudinal one. The coloring principle obtained from cochineal is carminic acid. (See *carmine*, 3.) *East Indian cochineals*, so called, are smooth glistening black grains, of no value; they are used to adulterate the genuine, which are easily distinguishable from them.

Female Cochineal (*Coccus cacti*); dried specimen of commerce. (Line shows natural size.)

2. The insect which produces the dyestuff known by the same name. See def. 1.—**Cochineal fig.** See *fig*.—**Cochineal paste.** See extract.

Cochineal paste is obtained by placing 10 lbs. of Honduras cochineal in a vessel, and adding 30 lbs. of ammonia water (17° B.), stirring the mixture well. The vessel should be covered with a cloth, and allowed to stand for a few days. The vessel is then to be immersed in boiling water, in order to evaporate the superfluous ammonia; when the evaporation is complete the mixture is ready to be used [for dyeing]. *W. Crookes*, Dyeing and Calico-printing, p. 88.

★**cochlea** (kok'lē-ä), *n.*; pl. *cochleæ* (-ē). [ML. (NL.), < L. *cochlea*, *coclea*, a snail, a snail's shell, < Gr. *κοχλίας*, a snail, etc., < *κόχλος*, a shell-fish with a spiral shell; prob. akin to *κόγχη*, L. *concha*, a conch, and ult. to E. *cockle*[2].] 1†. A winding staircase. *E. Phillips.*—2. In *anat.*, a part of the inner ear in most vertebrated animals. Its shape in man and most other mammals resembles a snail-shell; hence the name. In the petrous bone a canal winds about a central conical pillar of bone, the modiolus, and contains a hollow process of the membranous labyrinth; the latter follows the turns of the canal nearly to the top. To these structures taken together the name of *cochlea* is given. The process of the membranous labyrinth is triangular in cross-section, with its base applied to the outer wall of the canal and the apex attached to a spiral crest of bone, the lamina spiralis ossea, projecting from the inner side of the canal. It thus separates the bony canal into two portions, in addition to its own lumen, the scala vestibuli above and the scala tympani below. The lumen of the process itself is called the canalis cochlearis, its floor is called the basilar membrane, and its roof the membrane of Reissner. Its cavity is connected with the sacculus by the canalis reuniens. The essential structures of the cochlea, the rods of Corti and the hair-cells, are on the upper side of the basilar membrane, and to them is distributed the cochlear branch of the auditory nerve. NL. *cocus*, now *cocos*, > D. G. Dan. Sw. *kokos*- (in comp.), cocoa), prob. < Gr. *κόκκι*, the cocoa-tree, cocoanut; perhaps of Egyptian origin: cf. *κόϊξ*, an Egyptian kind of palm. The resemblance of the Sp. Pg. name to Sp. Pg. *coco*, a word used to frighten children, a bugbear, is prob. accidental. The spelling *cocoa* is due to confusion with *cacao*, which is also spelled *cocoa:* see *cocoa*[2].] A palm belonging to the genus *Cocos*, producing the cocoanut. *C. nucifera* is everywhere cultivated in tropical regions, but more especially on islands or near the sea. It has a cylindrical stem rising to a height of 60 to 90 feet, and surmounted by a crown of feather-like leaves from 18 to 20 feet long. The small white flowers grow on a branching spadix, inclosed in a hard tough spathe. The fruits, called *cocoanuts*, are in bunches of from 12 to 20, and are of a subtriangular ovoid form, 12 inches long by 6 broad. They have each a single seed inclosed in a very hard shell, and surrounded by a thick fibrous rind or husk. This fiber, called *coir*, is made into cordage, matting, brushes, bags, etc. The flesh or meat of the cocoanut is a white pleasant-tasting mass, soft and gelatinous when young, but afterward lining the shell in a thick close layer; it is largely used as a condiment and in cookery and confectionery, and yields the valuable cocoanut-oil (which see). The nut also contains when fresh from one to two pints of a clear pleasant liquid called the *milk*. The mature shell takes a high polish, and is made into drinking-cups and other utensils and ornaments. Its various uses make the cocoanut an important article of commerce. A spirit called *toddy* or *arrack* is made from the sweet juice of the spathe. Indeed, almost every part of the tree is employed in tropical countries for some useful purpose. The heart, which is seldom sound, is of a light yellowish-brown color, which changes to a deep brown, almost black. The firm part of the trunk is the so-called porcupine-wood, which is very hard and durable, and is much used for all kinds of turnery, and especially for inlaying. Also called *cocoa-tree, cocoanut-tree*.

The fruit often weighs 40 or 50 pounds, and usually contains 4 nuts, which are 18 inches long, lobed at each end. Before maturing the inside of the nut is soft and eatable. The hard black shell is carved into ornaments, the young leaves yield an admirable material for baskets and plaited work, and the older leaves are used for partitions and thatching. The nuts, driven across the sea by the monsoons, were known in India long before the discovery of the tree which produced them, and wonderful stories were current respecting their origin.—**Sea-cocoanut**, of Jamaica, the fruit of a species of *Manicaria*, a palm of Trinidad and the South American coast, often washed ashore upon that island.

cocoanut-oil (kō′kō-nut-oil), *n.* An oil obtained from the fruit of the *Cocos nucifera*, or cocoa-palm. It is prepared by the natives of the tropics, where the fruit abounds, both by decoction and by expression, and is used for lighting, the preparation of unguents, etc. It is exported to a considerable extent, and is also manufactured in Europe and the United States from cocoanuts or from copra, by expression or by treatment with sulphid of carbon. Chemically, it consists of a peculiar substance, cocinin, with a small quantity of olein. By saponification cocinin yields glycerin and cocinic acid. The oil is white, of the consistence of lard, and has a texture somewhat foliated. It is largely used in the preparation of candles and the so-called fulling-soaps. Also called *cocoa-oil*.

★**cod**[2] (kod), *n.* [< ME. *cod* (rare; cf. dim. *codling*[2]), of uncertain origin. Perhaps a particular application of ME. *cod*, a shell, husk, bolster: see *cod*[1], *n.* Wedgwood cites Flem. *kodde*, a club, and compares It. *mazza*, a club, with *mazzo*, a bunch, also a codfish; It. *testuto*, F. *testu*, applied to the codfish (and other fish), It. *testa*, F. *teste*, head. The orig. L. sense (*testa*, pot, shell, etc.) would support the derivation from *cod*[1], shell.] 1. The common English name of the *Gadus callarias*, an anacanthine fish of the family *Gadidæ*, and its best-known representative. It is a valuable food-fish, and is widely distributed throughout the northern and temperate seas of both hemispheres, but does not enter the Mediterranean, though found as

far south as Gibraltar. The principal cod-fisheries are on the banks of Newfoundland and the coasts of New England, but very valuable ones also exist on the coasts of Norway. It is a very voracious fish, living in water from 25 to 50 fathoms deep, where it always feeds close to the bottom, and will take almost any kind of bait which may be offered. The cod reaches maturity at the end of the third year, when it usually measures about 3 feet in length and weighs from 12 to 20 pounds; individuals, however, have been taken weighing from 50 to more than 100 pounds. The cod is of great commercial importance both as a food-fish and as the source of cod-liver oil, which possesses nutritive and therapeutic qualities of much value. Some variations in the size or quality of cod are indicated by terms expressive of the location in which they are taken, as *deep-water* or *shoal-water cod*, *shore* or *inshore cod*, etc. The name is also extended, as a popular family term equivalent to *Gadidæ*, to all the species, and in different English-speaking countries is misapplied to various species of scorpænids, chirids, serranids, sparids, percophidids, and ophidiids.

2. A hexagrammoid fish, *Ophiodon elongatus*, of the Pacific coasts of North America, universally called *cod* and *codfish* where the true cod is unknown. (*b*) Misapplied at San Francisco to various species of *Sebastodes* and *Sebastichthys*.

The name *Rock cod* applied [along the Pacific coast] to other Chiroids and to Sebastichthys, and thence even transferred to Serranus, comes from an appreciation of their affinity to Ophiodon, and not from any supposed resemblance to the true codfish. *Jordan*.

(*c*) A serranoid fish, *Acanthistius sebastoides*, of South Africa. (*d*) A percophidoid fish, *Parapercis colias*, of New Zealand.—**School cod**, cod occurring in large schools.—**Worm-cod**, cod feeding largely on worms and found near shore. (See also *cultus-cod*, *tom-cod*.)

A manuscript volume, complete or fragmentary, as of a classic work or of the sacred Scriptures. The most famous codices of the Greek Bible are the following uncial manuscripts: the *Sinaitic Codex*, of the fourth century, found by Tischendorf in 1844 and 1859 at the convent of St. Catharine on Mt. Sinai, and now in St. Petersburg (part in Leipsic); the *Vatican Codex*, also of the fourth century, in the Vatican library at Rome (contained in its first catalogue, 1475); the *Alexandrine* or *Alexandrian Codex*, of the fifth century, given to the patriarchate of Alexandria in 1098, and presented by Cyril Lucar, of that see and afterward of Constantinople, to Charles I. of England in 1628, and now in the British Museum; the *Codex Guelferbytanus*, or *Wolfenbüttel fragments*, of the fifth or sixth century, recovered from a palimpsest of Isidore of Seville; the *Codex Claromontanus*, or Clermont manuscript of St. Paul's epistles, now in Paris, a palimpsest of the sixth century, written over the Phaëthon of Euripides, etc. The most important manuscript of the Vulgate is the *Codex Amiatinus.* The copy of the Gothic Bible known as the *Codex Argenteus* (silver manuscript) from its silver letters (initials and divine names in gold), formerly at Werden in Westphalia, now at Upsala in Sweden, is noted both for this peculiarity and as being the most important of the few extant remains of the Gothic language. Among secular books, one of the most celebrated is the *Codex Ambrosianus* of the Iliad, containing 58 pictures, of all existing manuscript illustrations retaining most of the character of good antique art.

Till the 8th century, when it fell altogether into disuse, the Estrangelo continued to be employed for uncial manuscripts and ornate *codices.*

Both those who affirm and those who deny the expediency of codifying the English law, visibly speak of *Codification* in two different senses. In the first place, they employ the word as synonymous with the conversion of Unwritten into Written Law. *Codification* is, however, plainly used in another sense, flowing from the association of the word with the great experiment of Justinian, . . . to give orderly arrangement to this written law—to deliver it from obscurity, uncertainty, and inconsistency—to clear it of irrelevancies and unnecessary repetitious—to reduce its bulk, to popularize its study, and to facilitate its application. *Maine*, Village Communities, p. 362.

The nervous system is very indefinite, except in certain medusæ, and there is no proper blood-vascular system. Peculiar stinging-organs, thread-cells, cnidæ, or nematocysts are very generally present (in all the *Cnidaria* or cœlenterates proper), and in most cases the arrangement of parts or organs is radiate, as is especially observable in the disposition of tentacles around the mouth. Reproduction is usually sexual, distinct generative organs being present, the ova and spermatozoa being discharged by the mouth; but multiplication also takes place by budding and fission. The *Cœlentera* proper, or *Cnidaria*, are divided into the two great classes of *Actinozoa* and *Hydrozoa*, including all the sea-anemones, corals, acalephs, medusas, etc. In a wider sense, the sponges and ctenophorans are also included.

Pg. *café* = It. *caffè*, < Turk. *qahwe* (pronounced *kahve*), < Ar. *qahwe*, *qahwa*, coffee (as a liquid); cf. Ar. *bonn*, the coffee-berry.] **1.** The berry of trees belonging to the genus *Coffea*, of the family *Rubiaceæ*. Several species, but principally *C. Arabica*, produce the coffee of commerce. It is a native of Arabia and Abyssinia, but is now extensively cultivated throughout tropical countries. It will grow to the height of 16 or 18 feet, but is seldom permitted to exceed 8 or 9 feet, for the convenience of gathering the fruit. The stem is upright, and covered with a light-brown bark; the branches are horizontal and opposite. The flowers grow in clusters at the bases of the leaves, are pure white, and of an agreeable odor. The fruit is a small, red, fleshy berry, having the size and appearance of a small cherry. Each berry contains two seeds, commonly called *coffee-beans* or *coffee-nibs*. When ripe the berries are gathered, and the outer pulp and the parchment-like covering of the seeds are removed. The Mocha coffee from Yemen in Arabia is reputed the best; but the principal supplies are now obtained from Ceylon, Java, the West Indies, Brazil, and Central America. The Liberian coffee-tree, *C. Liberica*, of western tropical Africa, has recently been introduced into cultivation. It grows to a greater size and yields a much larger berry than *C. Arabica*, and thrives in low damp regions where the latter will not flourish. What is known as the *male coffee-berry* is simply a result of the occasional coalescence of the two seeds of the fruit into one, and differs in no other respect from the ordinary berry. The name *cherry-coffee* is given to the coffee-berry as it comes from the tree, before the pulp has been removed or the seeds have been dried.

Fruiting Branch of Coffee-plant (*Coffea Arabica*).
a, flower; *b*, section of berry, showing inclosed nutlets and position of embryo.

2. A drink made from the seeds of the coffee-tree, by infusion or decoction. Before being used the seeds are roasted, and then ground in a coffee-mill, or, as in the East, pounded. The beverage is best when made with coffee-beans freshly roasted and ground. Coffee acts as a slight stimulant, promoting cheerfulness and removing languor; but in some cases it induces sleeplessness and nervous tremblings. The use of it originated in Abyssinia, passed to Arabia several centuries later, and is said to have been made known in Europe by A. Rauwolf, a German physician, whose travels appeared in 1573.

3. By extension, something made in imitation of, used as a substitute for, or thought to resemble coffee: as, crust *coffee*.—**4.** A light meal resembling afternoon tea, at which coffee is served.—**5.** The last course of a dinner, consisting of black coffee.

The *coffee-house* must not be dismissed with a cursory mention. It might indeed, at that time, have been not improperly called a most important political institution. . . . The *coffee-houses* were the chief organs through which the public opinion of the metropolis vented itself. . . . Every man of the upper or middle class went daily to his *coffee-house* to learn the news and discuss it. Every *coffee-house* had one or more orators, to whose eloquence the crowd listened with admiration, and who soon became what the journalists of our own time have been called—a fourth estate of the realm. *Macaulay.*

Cognation is . . . a relative term, and the degree of connexion in blood which it indicates depends on the particular marriage which is selected as the commencement of the calculation. If we begin with the marriage of father and mother, *Cognation* will only express the relationship of brothers and sisters; if we take that of the grandfather and grandmother, then uncles, aunts, and their descendants will also be included in the notion of *Cognation*; and following the same process a larger number of Cognates may be continually obtained by choosing the starting point higher and higher up in the line of ascent. *Maine*, Ancient Law (3d Am. ed.), p. 142.

The act or state of cohering, uniting, or sticking together; specifically, in *phys.*, the state in which, or the force by which, the molecules of the same material are bound together, so as to form a continuous homogeneous mass. This force acts sensibly at insensible distances—that is, when the particles of matter which it unites are placed in apparent contact. At insensible distances it is a much greater, at sensible distances a much smaller, force than gravitation, so that it does not follow the law of variation of the latter. It unites the particles of a homogeneous body, and is thus distinguished from *adhesion*, which takes place between the molecules of different masses or substances, as between fluids and solids, and from *chemical attraction*, which unites the atoms of a molecule together. The power of cohesion in a body is estimated by the force necessary to pull its parts asunder. In general, cohesion is most powerful among the particles of solid bodies, weaker among those of liquids, and least of all, or entirely wanting, in elastic fluids, as air and gases. Hardness, softness, tenacity, elasticity, malleability, ductility, and in crystallized bodies cleavage, are to be considered properties dependent upon cohesion. The most powerful influence which tends to diminish cohesion is heat, as shown in the change of a solid to a liquid, or of a liquid to a gas, which is effected by it. See *gas* and *liquid.*

2. In *bot.*, the congenital union of one part with another. If the parts are similar, as two stamens, their union is specifically called *coalescence;* if dissimilar, as calyx and ovary, it is styled *adnation.*

3. Connection; dependence; affinity; coherence. [Now rare in this sense.]

Ideas that have no natural *cohesion.* *Locke.*

The greatest strength of that prevailing Faction [the Romish religion] lies in the close union and *cohesion* of all the parts together. *Stillingfleet*, Sermons, II. i.

Cohesion figures, a class of figures produced by the attraction of liquids for other liquids or solids with which they are in contact, and divided into *surface, submersion, breath*, and *electric cohesion figures.* It was found by C. Tomlinson, an English physicist, that a drop of liquid, as of oil or alcohol, spreads itself out on the surface of water always in a definite figure, the figure differing with each fluid dropped on the water; and he suggested that this might be employed as a test for oils, etc. The same principle holds true with regard to liquids which, from greater specific gravity, sink slowly to the bottom in water, each liquid submerged forming a definite figure peculiar to itself. *Breath figures* are produced by putting a drop of the liquid to be examined on a slip of mica and breathing on it, when again each fluid takes a distinct characteristic shape. *Electric cohesion figures* are produced by electrifying drops of various liquids placed on a plate of glass.—**Magnetic cohesion**, that power by which two magnetic bodies adhere together, as iron to a piece of lodestone.

Bronze Coinage Act, an English statute of 1859 (22 and 23 Vict., c. 30), making the coinage laws applicable to bronze or mixed metal coins.—**Coinage ratio,** the ratio which expresses the equivalence in value between gold and silver under the (then existing) mint law. Thus, in the United States, under the law of 1837, it is 15.988 to 1; that is, one pound of gold can be coined into as many dollars as 15.988 pounds of silver. The coinage ratio is intended (except for subsidiary coins), where bimetallism is desired, to be identical with the average commercial ratio; if this is not the case the metal which is undervalued disappears from circulation as money. Thus under the law of 1792 the coinage ratio was fixed at 15 to 1, but this undervalued gold and it disappeared from circulation; in 1834 the ratio was changed to 16.002 to 1, and in 1837 to 15.988 to 1, but this undervalued silver and it practically disappeared from circulation (except in the form of subsidiary and abraded coins) until 1873, when it was demonetized. Since that date the fall in the value of silver has brought the commercial ratio (1912) down to 34.13 to 1.—**Free coinage.** See *free.*—**Garbling the coinage.** See *garble.*

coke[1] (kōk), *n.* [Also written *coak*, and in E. dial. often in pl. *cokes, coaks*, cinders; a dial. pronunciation and use of *calk*, lime, chalk: see *chalk*. The term was applied to various light or porous minerals, and is latent in *charcoal*. Hence F. *coke*, Sp. *cok*, G. *koaks, kohks*, usually *coaks*, etc., coke.] The solid product of the carbonization of coal, bearing the same relation to that substance that charcoal does to wood. It is an important article in metallurgy, since few bituminous coals can be used for the manufacture of iron without having been first coked. The *coking coals*, as they are called, are bituminous, and such as contain but a small percentage of water. Hence the coals as recent as the Tertiary—brown-coals or lignites—rarely furnish coke; that is, the material left behind after the bituminous or volatile matter has been driven off is a powder, and not the coherent somewhat vesicular substance to which the name of *coke* is given. The nature of the difference between coking and non-coking coals has not yet been fully made out, and it is stated on good authority that some coal which cokes readily when first mined does not do so after having been exposed to the atmosphere, if only for a few days. The use of coke dates certainly as far back as the middle of the seventeenth century. Its preparation was formerly known as *charking* or *charring*, and the word was often, and is still occasionally, written *coak*.

coke-oven (kōk'uv″n), *n.* A furnace, oven, kiln, or retort used for reducing bituminous coal to coke; a coking-oven. At the present time there are two important types of coke-oven: in the beehive oven (which see, under *beehive*) the coal lies in a thin layer on the floor, and the gases distilled from it burn and furnish heat for further distillation until the same is completed. In the retort type of oven the coal is inclosed in a brick retort, and the gas distilled from it, or from that in a near-by retort, is burned around the outside.

A collect is composed of an address to the Trinity or to one of the Divine Persons, a petition thus introduced, and the pleading of Christ's merits or final ascription to a Person of the Trinity. One collect may be used alone or several in succession. Collects regularly belong to the eucharistic office, but are repeated in the day-offices (hours, morning and evening prayer), thus forming a constant link between the latter and the altar service. They are characteristic of Western liturgies and offices, not being known in the Eastern churches. Almost all those still in use are very ancient, and the origin of this form of prayer is at least as old as the fifth century. Leo the Great (440–61) and Gelasius I. (492–96) are reputed the first composers of collects. See *oratio*.

As used in current speech, and also in economics, no very definite line of distinction between communism and socialism can be drawn. Socialism, p. 140.

When the solution is applied to the wound, it immediately dries in a semi-transparent, tenacious film, which adheres firmly to the part, and protects the wound or abrasion. With the addition of a small quantity of iodides and bromides, collodion is employed as the basis of a photographic process, called the *collodion* or *wet process*. To obtain a negative picture by this process, a glass plate is covered with a film of collodion, which is sensitized by a salt (usually the nitrate) of silver, and the plate exposed in the camera. The latent image obtained is then developed by the application of a solution of iron protosulphate, water, and acetic acid, and the unprecipitated silver remaining in the film is dissolved by a fixing solution of sodium hyposulphite or of potassium cyanide. To obtain a positive picture, a sheet of paper is laid upon the face of the negative in a frame, the paper having been sensitized by the application of a silver salt, or by any other of several methods. The frame is then exposed to light in such a manner that the rays, to reach the paper, must pass through the negative, and the exposure is continued till the tone is sufficiently deep, after which the tint is improved by means of gold chlorid and other salts, and the picture fixed with sodium hyposulphite. Positive pictures may also be obtained direct by the collodion process. Collodion is used also as a water-proof coating in place of varnish, especially to protect lucifer matches from the effects of dampness.

II. *n.* A substance dissolved or suspended in a liquid medium and existing in a peculiar state of aggregation characterized by particles which, though still invisible to the eye, are too large to pass through parchment or other animal membranes; also, the gelatinous, slimy, or flocculent substance which separates from such a solution or suspension upon cooling, evaporation, or the addition of salts. Colloids in solution or suspension are further characterized by slow diffusibility, small osmotic pressure, slight influence upon the freezing- or boiling-point of the solvent, and motion under the influence of an electric current. Two classes of colloids may be differentiated: those which, like gelatin or silicic acid, greatly increase the viscosity of the solvent, even up to the point of producing a jelly, and which are not readily coagulated by salts, but gelatinize upon cooling or concentration; and those which, like colloidal gold or ferric hydroxid, do not possess any of these properties, but are readily coagulated by salts, and migrate with an electric current far more rapidly than those of the other class.

analysis of a rhythmical period into cola or sections. See *colon*[1], 2.—2. In *paleography*, measurement of manuscripts by cola or lines of determinate length; stichometry. See *stichometry* and *colon*[1], 3.

colon[1] (kō′lon), *n.*; pl. *cola* (-lä) in senses 1, 2, and 3, *colons* (-lonz) in sense 4. [= D. *colon* = G. Dan. Sw. *kolon* = F. Sp. Pg. *colon* = It. *colon, colo*, < L. *cōlon*, a member of a verse or poem, < Gr. *κῶλον*, a member, limb, clause, part of a verse.] **1.** In *anc. gram.* and *rhet.*, one of the larger or principal divisions of a sentence or period; a long clause, or a group of minor clauses or commata. See *comma*, 1.—**2.** In *anc. pros.*, one of the members or sections of a rhythmical period, forming an uninterrupted sequence of feet, united under a principal ictus or beat: sometimes called a *series*. A colon could not consist of more than 6 trisemic, 5 tetrasemic or pentasemic, or 3 hexasemic feet. It usually corresponded to one of the lines of a modern couplet, triplet, or stanza, or formed part only of a longer line. A *pure colon* is a colon consisting of feet of one kind only; a *mixed colon* is composed of feet of different kinds. See *period*.

3. In *paleography*, a long clause or group of clauses, or a series of words of about the average length of such a group, estimated as approximately equal to a dactylic hexameter in extent—that is, as containing from 12 to 17 syllables. A colon in this sense was frequently written as a separate line in manuscript, and served to measure the length of a book or treatise. See *colometry* and *epos*.

4. A mark of punctuation formed by two dots like periods placed one above the other (:), used to mark a discontinuity of grammatical construction greater than that indicated by the semicolon and less than that indicated by the period. The colon is commonly used (1) to emphasize a close connection in thought between two clauses of which each forms a complete sentence, and which might with grammatical propriety be separated by a period; (2) to separate a clause which is grammatically complete from a second which contains an illustration or amplification of its meaning: thus, in this work illustrative clauses introduced by "as" are separated from the definition by a colon; (3) to introduce a formal statement, an extract, a speech in a dialogue, etc. Originally it was the mark of the termination of the grammatical or paleographic division called by the same name, and it is now frequently used to mark off metrical periods in prose intended for chanting.

colon[2] (kō′lon), *n.*; pl. *colons* (-lonz), *cola* (-lä). [= D. *colon* = G. Dan. Sw. *kolon* = F. Sp. Pg. *colon* = It. *colon*, < L. *cōlon, cōlum* (prop. *cŏlon, cŏlum*), < Gr. *κόλον* (sometimes incorrectly written *κῶλον* by confusion with *κῶλον*, a member: see *colon*[1]), the large intestine, also food, meat, fodder. Hence *colic*.] **1.** In *anat.*, a portion of the intestinal tract, the so-called "large" as distinguished from the "small" intestine, continuous from the ileum to the rectum; the great gut, beginning at the cæcum and ending in the sigmoid flexure. In man and mammals generally the colon is distinguished from the preceding small intestine by its greater caliber, and by its sacculation, due to the particular distribution of its circular muscular fibers, which constrict it at some places and allow it to bulge out at others, making a series of pouch-like expansions. It may also present continuous bands of longitudinal fibers, or lengthwise constrictions, so that the cross-section is not circular. The colon may not be distinguishable in size or appearance from the rest of the intestine, as in birds, where its commencement is marked only by the presence of a cæcum or of two cæca; and when these are wanting, there is no distinction. In man the course and situation of the colon are definite, owing to the binding of the gut in place by the mesocolon and gastrocolic omentum. Beginning at the cæcum and ascending by the right kidney, it passes under the concave surface of the liver and the bottom of the stomach to the spleen; thence descending by the left kidney, it passes in the form of an S to the upper part of the sacrum, where it becomes the rectum. The parts of the colon are designated according to their position or direction: as, the *right lumbar* or *ascending colon*; the arch of the colon, or *transverse colon*; the *left lumbar* or *descending colon*; and the sigmoid flexure, or *left iliac colon*. See cuts under *alimentary* and *intestine*.

2. In *entom.*, the second portion of an insect's intestine, generally broader than the preceding portion or ileum. It may be straight or convoluted, terminating at the anal opening, or separated from it by a short rectum.

The change of *l* to *r* in the Sp. Pg. form is due to dissimilation, or perhaps to association with Sp. L. *corona*, Pg. *corõa*, a crown; cf. Sp. dim. *coronel*, a crown (in heraldry): see *coronal*. The E. word, orig. pron. as spelled, *cor-o-nel′*, *cor′o-nel*, became, by regular phonetic change, *cor′nel*, and now *cur′nel* (kėr′nel) (being often so spelled in novels and character sketches which seek to be realistic), retaining the *r* of its Sp. form; but the spelling was soon changed to suit the F. form, which was much more familiar to the eye of readers. Hence the later occasional pronunciations kol-ō-nel′, kol′ō-nel.] The chief commander of a regiment of troops, whether infantry or cavalry, next in rank below that of a general officer—in the United States army, of a brigadier-general. In the British army, except in the artillery and engineers, the office of colonel is often honorary, and is generally conferred on distinguished officers and princes of the blood royal, the real command resting with the lieutenant-colonel in each battalion, who after five years of service becomes a colonel. Generals who have had what is called "a regiment given to them" as a reward for service, and virtually as a retirement, have the rank of colonel. In the Russian, German, and Austrian armies the colonel of each regiment, holding the title only as an honor, is usually a member of some princely or other eminent family, often foreign, and sometimes appointed in childhood. Often, as a title, abbreviated *Col.*

Colonel Bogie. In *golf*, an imaginary player, to whom is assigned, by the committee in charge, a score against which the players have to play.

This "*Bogie*" score usually represents par play over the green, and it is made known before the competition begins, so that each competitor knows what he has to do at every hole. Each player counts his score at every hole, and if he holes out at that particular hole in fewer strokes, or in the same number, or in more than the appointed number, he wins, halves, or loses the hole to "Bogie," as the case may be. At the end of the game the number of holes won from "Bogie" are placed against those lost to "Bogie," and the player who is the greatest number of holes up or the fewest down wins the competition.

★**colony** (kol′ō-ni), *n.*; pl. *colonies* (-niz). [Early mod. E. *colonie*; = D. *kolonie* = G. *kolonie* = Dan. Sw. *koloni*, < F. *colonie* = Sp. Pg. It. *colonia*, < L. *colonia*, a colony, < *colonus*, a husbandman, colonist, < *colere*, till, cultivate, dwell: see *cult*, *cultivate*, etc.] 1. A company or body of people who migrate from their native country or home to a new province, country, or district, to cultivate and inhabit it, but remain subject to or intimately connected with the parent state; also, the descendants of such settlers so long as the connection with the mother country is retained.

Among the ancient Greeks the simple colony, which was not necessarily dependent upon the parent state except in religious matters, must be distinguished from a *cleruchy* (which see). Among the Romans the earliest colonies, so called, were merely garrisons in a hostile territory. Later, colonies were founded for the benefit of the poor of Rome; but Sylla restored the military character to the colony, which became in general a foundation for the benefit of veteran soldiers who had served their time. The colonists retained their Roman citizenship, and received their lands by lot, the original inhabitants of the site being subordinated to them. In American history the name is given especially to the thirteen separate communities along the Atlantic coast under English rule which combined in the revolution, and were formed in 1776 into the United States of America. They were (in geographical order) New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Delaware, Virginia, North Carolina, South Carolina, and Georgia. These were all originally English colonies excepting New York and Delaware, which were for a time respectively Dutch (as New Netherland) and Swedish (as New Sweden). Their governments were by charter (in Massachusetts, Rhode Island, and Connecticut), proprietary (in Pennsylvania, Delaware, and Maryland), or royal (in the remaining colonies). In each (except Rhode Island and Connecticut, which chose their own governors) the governor was appointed by the crown or by the proprietaries. The crown claimed a veto on legislation, and jurisdiction of appeals from the court of last resort.

Once on a time thirteen famous *colonies* of the older England voted that they were and ought to be free and independent States. By that vote they ceased, in the sense of a colonial office, to be English *colonies* any longer. In the sense of history they became English *colonies* more truly than before. *E. A. Freeman*, Amer. Lects., p. 25.

(*b*) In *zoöl.*, a polyp-stock, polypidom, or some similar aggregate of individuals: applied to various actinozoans, hydrozoans, and polyzoans, to the social or compound ascidians, etc. Thus, a bit of living coral is a *colony* of coral polypites. See cut under *Coralligena*.—**Crown colony**, a colony in which the crown has the entire control of the legislation, while the administration is carried on by public officers under the control of the home government: distinguished from colonies having a constitution and representative government. Gibraltar and Hongkong are examples of British crown colonies.—**Old Colony**, specifically, the Plymouth Colony in Massachusetts, or the region once occupied by it: so called from having been the earliest settlement within the present limits of Massachusetts.

For the transfer of sense, cf. Gr. *χροιά*, *χρόα*, surface, skin, color.] 1. Objectively, that quality of a thing or appearance which is perceived by the eye alone, independently of the form of the thing; subjectively, a sensation, or the class of sensations, peculiar to the organ of vision, and arising from stimulation of the optic nerve.

The proper stimulus to the sensation of color is light radiated from a luminous body or reflected from the surface of a non-luminous body; but it can be induced by other means, as by an electric shock. When a ray of white light is analyzed, as by a prism, into parts each of a definite wave-length, the parts show the colors red, orange, yellow, green, blue, and violet, which form a continuous spectrum, each color shading gradually into the next. (See *light* and *spectrum*.) These colors have been termed *primary* or *simple*, though in fact all color impressions are psychologically simple. If the colors of the spectrum are recombined, white light reappears. Similarly, if two colors which lie near together in the spectrum are mixed (for example, if two rays of colored light are thrown upon the same spot so as to be reflected from it together), the intermediate colors are nearly produced. If, however, the colors are taken farther and farther apart in the spectrum, the mixture becomes gradually whiter (less saturated) until two colors are found which produce a sensation of colorless light or gray. If the extreme colors of the spectrum are mixed, a purple results. Those pairs of colors which when mixed produce white or gray light are called *complementary* or *antagonistic colors*; such are red and verdigris, orange and greenish blue, yellow and blue, green-yellow and violet, green and purple, bluish green and carmine. The sensations produced by the different parts of the spectrum, however, vary with the intensity of the light: thus, with increased illumination the spectrum is seen as red, yellow, and blue; with decreased illumination, as red, green, and violet. If, instead of mixing spectral colors, colored pigments are mixed, very different results are obtained: thus, while spectral blue and yellow produce white, blue and yellow pigments produce green. This is due to the fact that the blue pigment absorbs nearly all the yellow and red light, while the yellow pigment absorbs the blue and violet light, so that only the green remains to be reflected. Colors vary in *chroma* or *saturation*, that is, in freedom from admixture of white light; in *brightness* or *luminosity*; and in *color tone* or *hue*, which roughly corresponds to the mean wave-length of the light emitted. The numbers which measure these quantities, as well as any other system of three numbers for defining colors, are called *constants of color*. Blacks, whites, and grays are not regarded in psychology as colors; but white and black objects are commonly spoken of as colored, although the former reflect and the latter absorb all the rays of light without separating them into colors properly so called.

2. In *painting*: (*a*) The general effect of all the hues entering into the composition of a picture. (*b*) An effect of brilliancy combined with harmony: said either of a work in different colors or of a work in monochrome, or of an engraving: as, the picture has no *color*; the engraving is full of *color*.

Though there is no *colour*, strictly speaking, in an engraving consisting merely of black and white lines, yet the term is often . . . applied to an engraving which is supposed, from the varied character of its lines and the contrast of light and shade, to convey the idea of varied local *colour* as seen in a painting. *Chatto*, Wood Engraving, p. 213.

3. Any distinguishing hue, or the condition of having a distinguishing hue—that is, a hue different from that which prevails among objects of the kind concerned, whether the prevailing hue be positive, as green, or neutral or negative, as white or black; hence, (*a*) in a picture or view, or in a fabric or other material dyed or painted, any hue, especially a pure tint (often implying a vivid one), other than black and white; (*b*) in human beings, from the standpoint of the white races, a hue or complexion other than white, and especially black; (*c*) in *bot.*, any hue except green. See *colored*, 2.—4. The natural hue of the face; a red or reddish tint; flush; blush; complexion in general.

These colors are widely used in Anglican churches also, though less frequently for vestments than for hangings. Some Anglican churches have revived the old English or Sarum colors, namely, red as the ordinary Sunday color, as a penitential color on Ash Wednesday, Good Friday, Easter Even, and Whitsun Even, and also on the same days as in the Roman use; white, throughout Eastertide; yellow, for feasts of confessors; blue, indifferently with green; and brown or gray with violet, for penitential seasons. When pressed into molds and thoroughly dried, they are called *cake-colors*; but when sold in the form of a stiff paste they are called *moist colors*. (*b*) A painting done in such pigments.—**Young-Helmholtz theory of color** [named for Thomas Young (1773–1829), who, however, only suggested the theory, and Hermann Ludwig Ferdinand von Helmholtz (1821–1894)], the doctrine that there are three kinds of nerves in the retina, giving the primary sensations of red, green, and violet, and that all other color-sensations are due to the simultaneous excitation of two kinds of nerves or of all three. = **Syn. 1.** *Shade, Tint*, etc. See *hue*[1].—**10.** Plea, pretext, semblance, disguise.

★**color-blindness** (kul'ọr-blīnd″nes), *n.* Incapacity for perceiving colors, independent of the capacity for distinguishing light and shade, and form. It is not a mere incapacity for distinguishing colors (for this might be due to want of training), but an absence or great weakness of the sensations upon which the power of distinguishing colors must be founded. Color-blindness may be *total,* that is, the absence of all perception of colors as such, independently of light and shade, all colors appearing simply as shades; or *partial,* the entire or partial inability to distinguish particular colors independently of difference of light and shade. The most common form of the latter defect is the inability to perceive red as a distinct color, red objects being confounded with gray or green, and next in frequency is the inability to perceive green. The color which to a normal eye is complementary to the defective color appears as gray; and a mixture of white and black (gray) of the proper luminosity certainly cannot be distinguished by the color-blind from the defective color (red or green). The results of statistical inquiries as to the prevalence of color-blindness show its existence in from 2 to 6 per cent. of males, while among women the number of cases seems to be considerably under 1 per cent. Also called *daltonism* and *achromatopsia.*

Specific categories of color-variation are *albinism*, *melanism*, and *erythrism*. (See these words.) The regular occurrence of some kinds of color-variation is called *dichromatism*, examples of which are the gray and red phases of many owls, and the white or colorless and variously colored phases of many herons. D. 80. A large portion of the structure still exists, part of the wall being entire. The outline of the Colosseum is elliptic, the exterior length of the building being 607 feet, and its breadth 512 feet; it is pierced with 80 vaulted openings or vomitories in the ground story, over which are superimposed on the exterior face three other stories, the whole rising perpendicularly to a height of 159 feet. The lower story is decorated between the arches with Doric semi-columns; the second and third stories, also with arched openings, bear respectively Ionic and Corinthian semi-columns; and the fourth story, which is higher than the others, and walled in, bears an equal number of Corinthian pilasters, and is pierced in alternate intercolumniations with rectangular windows, and in the remaining intercolumniations with smaller rectangular openings at a lower level. The arena is 253 by 153 feet, and covers extensive substructions provided for the needs and machinery of ordinary gladiatorial displays, and for the flooding of the arena to convert the amphitheater into a place for naval contests when required. A system of awnings was provided for shading the entire interior. It is estimated that the Colosseum provided seats for 87,000 spectators. The exterior of the building is faced with blocks of travertin; the interior is built of brick, with considerable use of marble. See *amphitheater*.

(*c*) A bone of the side of the skull of some reptiles, especially lizards, a peculiar dismemberment of the pterygoid, which may meet the parietal or a process of it; the column-bone; the columella cranii. Its presence in nearly all lizards gives rise to the term *Cionocrania*, or "column-skulls," as a major division of *Lacertilia*. See cuts under *acrodont* and *Cyclodus*.

In the principal group of the Lacertilia, a column-like membrane bone, called the *columella*, . . . extends from the parietal to the pterygoid on each side, in close contact with the membranous or cartilaginous wall of the skull. . . . This *columella* appears to correspond with a small independent ossification, which is connected with the descending process of the parietal and with the pterygoid, in some Chelonia. *Huxley*, Anat. Vert., p. 189.

Columns are distinguished by the names of the styles of architecture which they represent: thus, there are Egyptian, Grecian, Roman, and medieval columns. In classic architecture they are further distinguished by the names of the orders to which they belong, as Doric, Ionic, or Corinthian columns; and again, in various styles, by some peculiarity of position, of construction, of form, or of ornament, as attached, twisted, cabled or rudented, and carolitic columns. Columns are used chiefly in the construction or adornment of buildings. They are also used singly, however, for various purposes: as, the *astronomical column*, from which astronomical observations are made; the *chronological column*, inscribed with a record of historical events; the *gnomonic column*, which supports a dial; the *itinerary column*, pointing out the various roads diverging from it; the *milliary column*, set up as a center from which to measure distances; the *triumphal column*, dedicated to the hero of a victory, etc.

Combs are used for arranging the hair in dressing it; also, in a great variety of ornamental forms, for keeping women's hair in place after it is dressed; and for various other purposes. Those worn in the hair are often carved and elaborately decorated.

3. The fleshy crest or caruncle growing, in one of several forms, on the head of the domestic fowl, and particularly developed in the male birds: so called from its serrated indentures in the typical form, or single comb, which resemble the teeth of a comb. Several characteristic variations in the form of the comb have received distinctive names. An *antlered comb* is one having more or less the form of a stag's antlers, as seen in Polish and La Flèche fowls, often in Houdans, etc. The *leaf-comb* has much the form of a strawberry-leaf, set transversely on the head. It is the preferable form of comb in Houdan fowls. The *pea-comb* appears as if formed of three low, bluntly serrated combs set side by side on the head, the middle one of the three being the highest. It is the typical comb of the Brahma fowls. A *rose-comb* is a low comb set flat on the head, like a cap, broad in front, and tapering to a projecting spike behind, the upper part being evenly covered with small projections. It is best illustrated in the Hamburg fowls, and is also found in the Wyandotte, the Sebright bantam, and other varieties. The *strawberry-comb* resembles a half of a strawberry, generally somewhat wrinkled, and set well forward on the head. It is characteristic of the Malay and the Sumatra fowls.

Chemically considered, combustion is a process of rapid oxidation caused by the chemical union of the oxygen of the air, which is the supporter of combustion, with any material which is capable of oxidation—that is, combustible. It results in the formation of oxygen compounds, some or all of which may be gaseous and therefore invisible, and in the liberation of energy, which is made evident by a rise of temperature and often by flame or incandescence. The weight of the products of combustion is always precisely equal to the sum of the weight of the burned substance and that of the oxygen used in the burning. The energy set free is also precisely the same as that which would be required to separate the oxygen again from its combinations. In common life oxygen is the sole supporter of combustion. In the laboratory iodine, chlorin, and some other substances also perform a similar office in certain cases. The term *combustion* has also been applied to slow processes of oxidation not attended by high temperature or evolution of light, such as the combustion in the body which keeps up the animal heat, and the slow decomposition of animal and vegetable matter in the air. See *eremacausis.*

The compression of air renders the *combustion* of gaseous matter less perfect, and, . . . within certain limits at least, the more rarefied the atmosphere in which flame burns, the more complete its *combustion.*

E. Frankland, Exper. in Chem., p. 901.

Any chemical action whatsoever, if its energy rise sufficiently high, may produce the phenomenon of *combustion*, by heating the body to such an extent that it becomes luminous. *Fownes.*

W. Lilly, Introd. to Astrology, App., p. 339.

Spontaneous combustion, the ignition of a body without its temperature having been raised by the application of heat from an external source. It often takes place in heaps of rags, wool, or cotton soaked with oil, and in masses of wet coal. In the first case it is caused by the rapid spontaneous oxidation of oil, which raises the temperature sufficiently to make it burst into flame; in the second case a similar rapid oxidation of the sulphur of pyrites contained in coal causes an increase of heat sufficient finally to ignite the coal. See *flame.*

★**comet** (kom'et), *n.* [< ME. *comete*, < AS. *comēta* = F. *comète* = Pr. Sp. Pg. It. *cometa* = D. *komeet* = G. Dan. Sw. *komet*, < L. *cometa*, also *cometes*, < Gr. *κομήτης* (with or without *ἀστήρ*, star), a comet, lit. long-haired (so called from the appearance of its tail), < *κομᾶν*, wear long hair, < *κόμη*, hair: see *coma*[2].] 1. One of a class of celestial bodies which move about the sun in greatly elongated orbits, usually elliptical or parabolic. The typical comet, as it approaches the sun, has the appearance of a bright star-like point (the *nucleus*) surrounded by a mass of misty light (the *coma*), which is

Comet of Donati, October 3d, 1858.
(From "Annals of Harvard Observatory.")

extended away from the sun into a stream of light (the *tail*) reaching a length of from 2° to 90°. Comets which follow a parabolic orbit appear but once, their orbit being infinite, and are called *parabolic comets*; those moving in ellipses return periodically, and are called *periodic comets*. The fact of the periodicity of some comets was first established by Halley with reference to the comet of 1682. The paths in which they move are not, like those of the planets, all nearly in the same plane as the orbit of the earth, but are inclined to that orbit at all angles; and their motion along their paths is about as often retrograde as direct. Some comets have no nucleus; and this is the case with every one while it is still very remote, when it appears as a mere nebulous patch. In this state it is called a *telescopic comet*. As it approaches the sun, the nucleus is gradually formed as a central but not sharply defined point of light; later, the tail, consisting of vaporous matter driven back by some repellent influence of the sun, often with enormous velocity, is formed; and lastly, if the comet is a bright one, a series of bright envelops rises successively from the nucleus, each extending back into the tail, and gradually disappearing. The matter of which comets are composed is so transparent that the faintest stars are seen through them without the slightest diminution of their luster. Of their physical constitution little is definitely known. The most remarkable discovery of recent times regarding them is the identity of the course of some of them with the orbit of certain showers of shooting stars. This was first demonstrated by the Italian astronomer Schiaparelli, who proved the agreement between the orbit of the great comet of 1862 and that of the star-shower seen annually about August 1st–10th. Very remarkable comets appeared in 1456, 1680, 1811, 1843, 1858 (Donati's), 1861, 1874, and 1882. Halley's comet has a total period of from 75 to 79 years; it last appeared in 1910. See the supplement.

F. *commodore* is from E.] 1. An officer in the navy next in rank below a rear-admiral and above a captain. In the navy of the United States (in which the office was first created in 1862) a commodore ranked with a brigadier-general in the army, and might command a division or a squadron, or be chief of staff of a naval force commanded by an admiral or a vice- or rear-admiral; or he might command ships of the first class, or naval stations. The rank was abolished in 1899. In the British navy the rank of commodore is a temporary one, and of two kinds, of which the first conveys authority over a captain in the same ship, while the second does not. The former gives the rank, pay, and allowances of a rear-admiral; the latter, the pay and allowances of a captain. They both carry distinguishing pennants. Abbreviated *Com.*

Also called the *Hellenic dialect,* and distinguished on the one hand from pure Attic, which it approached more or less closely, and on the other from the Alexandrian and other local or Hellenistic dialects. The writings of Aristotle mark the transition from Attic to the common dialect, and Polybius is the earliest writer of note who employs it. Authors who exerted themselves to restore the common dialect as far as possible to the pure Attic standard are called *Atticists.* After the fourth century A. D. the common dialect changed gradually into Byzantine Greek.—**Common diligence.** See *diligence.*—**Common divisor.** See *divisor.*—**Common field.** (Generally in the plural.) The keeping of such a place is a criminal offense. In order to meet various devices to evade the letter of the law, the statutory definitions are usually minute, specifying a great variety of detail. The essential features of all or nearly all laws against common gaming-houses consist in the prohibition of maintaining a place of shelter in any degree accessible to the public, whether open to all who come or only to a select or favored few, as a place of resort for the purpose of gaming. See *gaming.*—**Common good,** in *Scots law,* in its widest sense, all the property of a corporation over which the magistrates have a power of administration solely for behoof of the corporation.—**Common land,** loosely, land owned in severalty but used in common; more strictly, land owned by the community, and, not being appropriated for the time to cultivation by any individual, used as waste or open land for common pasturage. See II., 3.—**Common law.** (*a*) In its most general sense, the system of law in force among English-speaking peoples, and derived from England, in contradistinction to the civil or Roman law and the canon or ecclesiastical law. (*b*) More appropriately, the parts of the former system which do not rest for their authority on any subsisting express legislative act; the unwritten law. In this sense common law consists in those principles and rules which are gathered from the reports of adjudged cases, from the opinions of text-writers and commentators, and from popular usage and custom, in contradistinction to statute law. (*c*) More narrowly, that part of the system just defined which was recognized and administered by the king's justices, in contradistinction to the modifications introduced by the chancellors as rules of equity in restraint or enlargement of the customary and statutory law (see *equity*), and, in respect of procedure, in contradistinction to the code practice.—**Common-law procedure acts,** three English statutes of 1852, 1854, and 1860 which simplified the forms of process, pleading, and practice in the superior courts.—**Common long meter,** in *psalmody,* a six-lined stanza combining a common-meter stanza with half of a long-meter stanza: thus, 8, 6, 8, 6, 8, 6. Also called *common hallelujah meter.*—**Common measure.** (*a*) See *common divisor,* under *divisor.* (*b*) In *music,* duple and quadruple rhythm. The usual sign (*A*) for these rhythms is derived from the theory of medieval musicians that duple rhythm was imperfect, and so to be indicated by a half or broken circle (*B*). It is not the initial of the word "common," since originally triple rhythm was regarded as the standard or perfect rhythm. The sign *A* now usually signifies quadruple rhythm, four beats to the measure, while *C* signifies duple rhythm, two beats to the measure. Also called *common time.*—**Common meter,** in *psalmody,* a form of iambic stanza, primarily of 4 lines, having alternately 8 and 6 syllables to the line: so called because it was the commonest stanza in early psalmody. *Double common meter* consists of a stanza with 8 lines having alternately 8 and 6 syllables.—**Common multiple.** See *multiple.*—**Common notion,** a notion applicable to several objects.—**Common nuisance.** See *nuisance.*—**Common particular meter,** in *psalmody,* a stanza with 6 lines, the third and sixth of which have 6 and the rest 8 syllables.—**Common pasturage,** in *Scots law,* a known rural servitude by which the owner of the dominant tenement is entitled to pasture a certain number of cattle on the grass grounds of the servient tenement.—**Common place** [tr. The three estates of clergy, lords, and *commons* finally emerge as the political constituents of the nation, or, in their parliamentary form, as the lords spiritual and temporal and the *commons*. This familiar formula in either shape bears the impress of history. The term *commons* is not in itself an appropriate expression for the third estate; it does not signify primarily the simple freemen, the plebs, but the plebs organised and combined in corporate communities, in a particular way for particular purposes. The *commons* are the "communitates" or "universitates," the organised bodies of freemen of the shires and towns; and the estate of the *commons* is the "communitas communitatum," the general body into which for the purpose of parliament those communities are combined. The term, then, as descriptive of the class of men which is neither noble nor clerical, is drawn from the political vocabulary, and does not represent any primary distinction of class. *Stubbs*, Const. Hist., § 185.

communism (kom′ū-nizm), *n.* [< F. *communisme*, < *commun*, common, + *-isme*: see *common*, *commune*[2], *n.*, and *-ism*.] 1. An economic system, or theory, which rests upon the total or partial abolition of the right of private property, actual ownership being ascribed to the community as a whole or to the state. The right of the state to control the means of production, and also the distribution and consumption of the products of industry, is in general especially emphasized by the advocates of the theory. In some communistic schemes the right of the individual to the control of his own labor is also denied, each one being required to do that which is most advantageous to the community as a whole. Such theories, differing in details, have frequently been advanced — by Plato in his "Republic," by Sir Thomas More in his "Utopia," and in recent times by many writers — and have not infrequently been carried into execution on a small scale, as in the Oneida Community. See *community*.

Communism, in its ordinary signification, is a system or form of common life in which the right of private or family property is abolished by law, mutual consent, or vow. To this community of goods may be added the disappearance of family life.

Woolsey, Communism and Socialism, p. 1.

Communism is the name that has been given to the schemes of social innovation which have for their starting-point the attempted overthrow of the institution of private property. *Encyc. Brit.*, VI. 211.

All *communists* without exception propose that the people as a whole, or some particular division of the people, as a village, or commune, should own all the means of production — land, houses, factories, railroads, canals, etc.; that production should be carried on in common; and that officers, selected in one way or another, should distribute among the inhabitants the fruits of their labor.

R. T. Ely, French and German Socialism, p. 35.

Discordant theories range from the doctrines of the *communist*, who would overturn our social structures, to those of the timid, half-hearted believers in our government, who wish to go back to restraints and powers exerted by the monarchs of Europe.

W. E. Hearn, Aryan Household, p. 240.

All other acquisitions during marriage are the joint property of both, and the husband has the active power of disposal during the life of both, the wife's rights being meanwhile passive. On the death of either, the survivor administers, much as in the case of partnership, the survivor being entitled to one half, and the heirs, etc., of the deceased to the other half. — **House community**, an early form of organization in which the heirs of a given ancestor and their heirs in turn continued to live together, upon the common inheritance, with a common dwelling and common table. — **Oneida Community**, a religious society or brotherhood, the *Bible Communists* or *Perfectionists*, established in 1847 on Oneida creek, in Lenox township, Madison county, New York, by John H. Noyes, after unsuccessful attempts to establish it at New Haven, Connecticut, in 1834, and at Putney, Vermont, in 1837. A branch of the Oneida Community also existed at Wallingford, Connecticut, but has now been withdrawn. Originally the Oneida Community was strictly communistic, all property and all children belonging primarily to the society, and the restrictions of marriage being entirely abolished; but in 1879, owing to the increasing demand of public opinion that the social practices of the society should be abandoned, marriage and family life were introduced, and in 1880 communism of property gave place to a joint-stock system, and the Community was legally incorporated as "the Oneida Community, Limited." — **Village community**, an early form of organization, in which the land belonged to the village, the arable land being allotted by it to the members or households of the community, by more or less permanent arrangements, the waste or common land remaining undivided.

7. An instrument used to indicate the magnetic meridian, or the direction of objects with reference to that meridian. The mariners' or ship's compass consists of three parts, viz., the *bowl*, the *card*, and the *needle.* The bowl, which contains the card and needle, is usually a hemispherical brass receptacle, suspended by two concentric brass rings (called *gimbals*) in such a manner that the bowl is kept in a horizontal position, notwithstanding the motion of the ship. The circular card is divided into 32 equal parts by lines drawn from the center to the circumference, the points of intersection with the circumference (or the radial lines, or *rhumbs*, themselves) being called the *points of the compass.* The intervals between the points are also divided into halves and quarters. The whole circumference is divided into 360 degrees; consequently, the angle between any two adjoining points is 11° 15′. The four principal divisions (dividing the circumference into four equal parts) are called the *cardinal points*, viz., north, east, south, and west. The names of the others are compounded of these; and if the direction or bearing referred to lies between any two points, quarter or half points are added, as N. E. by E. ½ E.; or it is expressed in degrees, as south 42° west. The needles, of which there are generally from two to four, fastened to the bottom of the card, consist either of laminæ or layers of hardened steel or of bundles of steel wire. In the center of the card is a conical socket poised on an upright pin fixed in the bottom of the bowl, so that the card hanging on the pin turns freely round its center. On shipboard the compass is so fixed that a black mark, called the lubber's line, coincides with an imaginary line parallel to the keel of the ship, and the point of the compass-card which is directly against this line indicates the direction of the ship's head. The indication is, however, subject to a certain modification, owing to the variation of the magnetic meridian (see *variation*) and the deviation of the needle caused by the iron in the ship (see *deviation of the compass*, under *deviation*). The regulation compass in the United States navy, and the one also used on many mail-steamers, is known as Ritchie's liquid compass, in which the card is a skeleton, and the bowl, having a glass top, after being filled with a fluid composed of about one third alcohol and two thirds water, is hermetically sealed.
